1.0 Introduction

AECOM has prepared this *Second Long-Term Monitoring (LTM) Report* to describe field and laboratory operations and analytical results during the April 2010 groundwater sampling event. The April 2010 sampling event represents the second semiannual LTM event at Site ST-14, Andrews Air Force Base (AFB), Camp Springs, Maryland (Figure 1-1). The United States Army Corps of Engineers (USACE) contracted AECOM, under Contract No. DACA45-03-D-0032, Contract Task Order No. 0027, to implement performance-based restoration at Sites ST-14 and SS-22, at Andrews AFB, Maryland.

As stated in the *Contract Performance Work Statement for Sites ST14 and SS22 at Andrews AFB* (June 2005), the performance objectives for Site ST-14 are to:

- Prevent further migration of the plume;
- Eliminate/treat identified source areas; and
- Sufficiently treat and demonstrate degradation of contaminants in groundwater, i.e., return groundwater to beneficial use (equal to or less than the maximum contaminant levels [MCLs]) within 20 to 30 years.

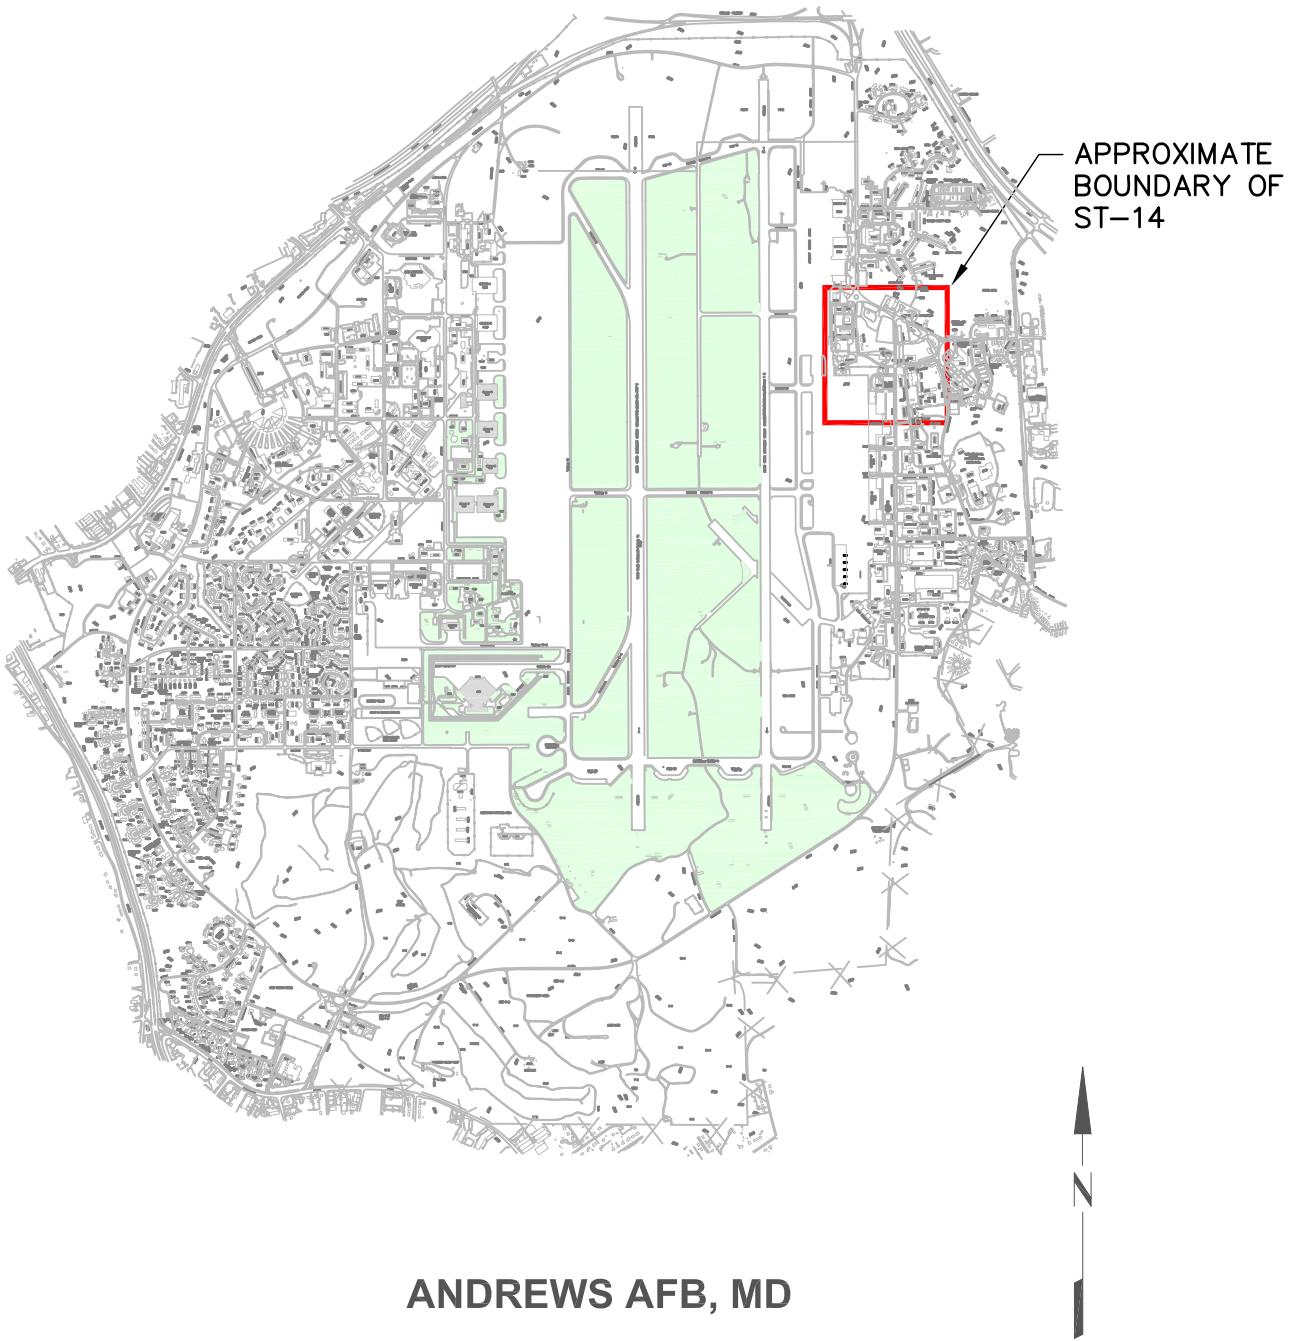

These performance objectives will be achieved through the implementation of the approved remedy, in-situ biodegradation and injection of carbon substrate with LTM, at Site ST-14.

1.1 Purpose

AECOM implemented the approved remedial action at Site ST-14 in October 2007. Remedial construction included installation of 195 injection points (IPs) and 24 monitoring points in accordance with the layout provided in the *Final Remedial Design Report* (Earth Tech, 2007d). Injection of sodium lactate was first performed at three areas during the Pre-Design Study (PDS) in 2006 to prove the effectiveness of the remedy and aid with determining the appropriate design parameters.

The purpose of this LTM event was to monitor concentration trends of trichloroethene (TCE); its breakdown products *cis*-1,2-dichloroethene (DCE) and vinyl chloride (VC); carbon tetrachloride (CT); and benzene, toluene, ethylbenzene, and xylenes (BTEX). The analytical and field parameter data collected during this and previous LTM events has been utilized to illustrate trends in dissolved groundwater concentrations of chemicals of concern (COC) and demonstrate the effectiveness of the implemented remedy.

Through April 2010, AECOM completed ten sodium lactate injection events at Site ST-14. The eighth, ninth, and tenth sodium lactate injection events included 14 new injection points installed in locations where reductions in TCE concentrations had not been achieved to date. The effects of these supplemental remedial actions are documented in this LTM report.

1.2 Scope

The activities conducted as part of this LTM event included:

- Sampling of 38 groundwater monitoring wells, temporary monitoring points (TMPs), and injection points (IPs), and three surface water locations (Figure 1-2);
- Laboratory analysis of the collected samples;
- Third party validation of the laboratory results for volatile organic compounds (VOCs);
- Evaluation of the laboratory results; and
- Preparation of this report with conclusions drawn from the analysis.

The sampling activities followed protocols presented in the *Site-Specific Safety and Health Plan (ST-14 and SS-22)* (Earth Tech, 2006a) and the *Field Sampling Plan for the Remedial Design/Remedial Action, ST-14 and SS-22* (Earth Tech, 2006b) for Andrews AFB.

DESCRIPTION			

2.0 Site History

The main base portion of Andrews AFB constitutes approximately 4,360 acres in northwestern Prince George's County, Maryland, and is located approximately 5 miles southeast of the District of Columbia. The Base has been in operation since the 1940s. Site ST-14 is located in the northeast portion of Andrews AFB, extending to the east and west of Perimeter Road (Refer to Figure 1-1). A full service fueling station with two bays was built on the Site in 1945. The gas station was closed and converted into a convenience store (the "Shoppette") in the early 1980s. The Cabin Branch creek, located north of the site, receives groundwater discharge from the surficial aquifer via seeps along its southern bank.

In 1983, the Maryland Department of the Environment (MDE) issued a Consent Order for the removal of two 10,000-gallon gasoline underground storage tanks (USTs). The two 10,000-gallon USTs, a 250-gallon waste motor oil UST, and petroleum-contaminated soil were removed from the site between 1983 and 1986. United States Geological Survey (USGS) investigations conducted between 1988 and 1989 confirmed the presence of BTEX contamination in the groundwater at Site ST-14. In 1992, a groundwater investigation conducted by Dames & Moore (D&M, 1992) reconfirmed the BTEX plume and identified the presence of TCE and CT plumes in groundwater at Site ST-14, originating upgradient (southwest) of the Former East Side Gas Station. In 1993, a 1,000-gallon steel UST containing No. 2 fuel oil was removed near Building 3471 (near Patrick Avenue). The Comprehensive Environmental Investigation (CEI), completed as part of the Remedial Investigation (RI) between April 1999 and November 2000, indicated that the TCE plume extended from the water table, located 15 to 20 feet below ground surface (bgs), to the Calvert Formation, a clay aquitard located at 38 to 40 feet bgs.

A lack of tetrachloroethene (PCE) detections in the site's groundwater led previous investigators to presume that TCE was the original contaminant and not a metabolic breakdown (i.e., daughter) product of PCE. This presumption is further supported by the fact that Andrews AFB widely used TCE as a degreaser through the 1960s. Two fire department wash sites, a former aircraft wash rack, and a former vehicle wash rack are all located within the boundary of Site ST-14 and represent potential sources of TCE contamination. These source areas were investigated in the *Final CEI* (IT, 2000). Contaminant concentrations in groundwater exceeded the federal MCLs for several compounds. However, analyses of surface water samples indicated that contaminant concentrations were less than applicable water quality standards or were not detectable. This has been attributed to volatilization and/or dilution of organic contaminants in surface water (Earth Tech, 2007d). The contaminant concentrations found in soil samples were not indicative of a continuing source for groundwater contamination.

3.0 Summary of Remedial Activities

AECOM designed remedial activities at Site ST-14 to address several TCE/CT contaminated areas within the site and BTEX in the northeast area of the site. To address TCE/CT contamination at Site ST-14, AECOM utilized enhanced reductive dechlorination (ERD) via injection of a carbon substrate (i.e., sodium lactate). Reductive dechlorination is the principal mechanism for transformation of chlorinated volatile organic compounds (CVOCs) under anaerobic conditions. Addition of a carbon substrate, such as sodium lactate, to the subsurface provides a growth substrate for the nitrate-reducing bacteria, sulfate-reducing bacteria, and methanogens required to create anaerobic conditions. Under such conditions, these microorganisms dechlorinate and reduce TCE to its intermediate metabolites, DCE and VC. These daughter products further reduce to ethene under aerobic conditions. CT also reduces under anaerobic conditions to chloroform. This metabolic pathway includes methylene chloride, methyl chloride, and methane.

To address the BTEX contamination in the northeast portion of Site ST-14, AECOM utilized enhanced biodegradation through injection of an oxygen-releasing compound (i.e., PermeOx® Plus). Through injection of an oxygen-releasing compound, AECOM intended to introduce additional electron acceptors to the system and accelerate the aerobic degradation of the contaminants.

Between May and October 2006, AECOM conducted a PDS to demonstrate the effectiveness of ERD. Section 3.1 briefly describes the PDS. The *Final Site ST-14 Remedial Design Report* (Earth Tech, 2007d) provides additional details of the remedial methods employed. Section 3.2 describes the full-scale sodium lactate injection events and Section 3.3 describes the PermeOx® Plus injection event.

3.1 Pre-Design Study Sodium Lactate Injections

In order to evaluate the effectiveness of ERD by injection of an organic carbon substrate (i.e., sodium lactate), AECOM conducted a 6-month PDS at three test areas, previously determined to be “hot spots” within the site. The PDS included installation of injection and monitoring wells, three injection events, and three groundwater sampling events. The *Final PDS Report* (Earth Tech, 2007a) includes details of all PDS activities. Following each injection round, AECOM monitored changes in total organic carbon (TOC), geochemical conditions, and microbial population to verify the development and maintenance of anaerobic, carbon-rich conditions that would be conducive to ERD. During the course of the PDS period, periodic injections of sodium lactate maintained elevated TOC concentrations at injection and monitoring points. The ERD process depleted dissolved oxygen (DO) following the injections, progressively establishing a stable reductive anaerobic treatment zone over 6 months that extended 15 to 20 feet downgradient from the injection points. Depletion of nitrate and a dramatic increase in methane (evidence of nitrate-reducing bacteria and methanogens) confirmed the presence of an anaerobic zone. Additionally, phospholipid fatty acid (PLFA) analyses indicated an increase in microbial biomass in the test areas.

Following substrate injection, reductions in TCE concentrations were observed in most monitoring wells, though changes in reduced daughter products (i.e., DCE and VC) were more variable. Concentrations of *cis*-1,2-DCE increased in all wells in Test Area 1, did not change significantly in the wells in Test Area 2, and decreased in all wells in Test Area 3. VC was only detected in one well (in Test Area 1) following substrate injections.

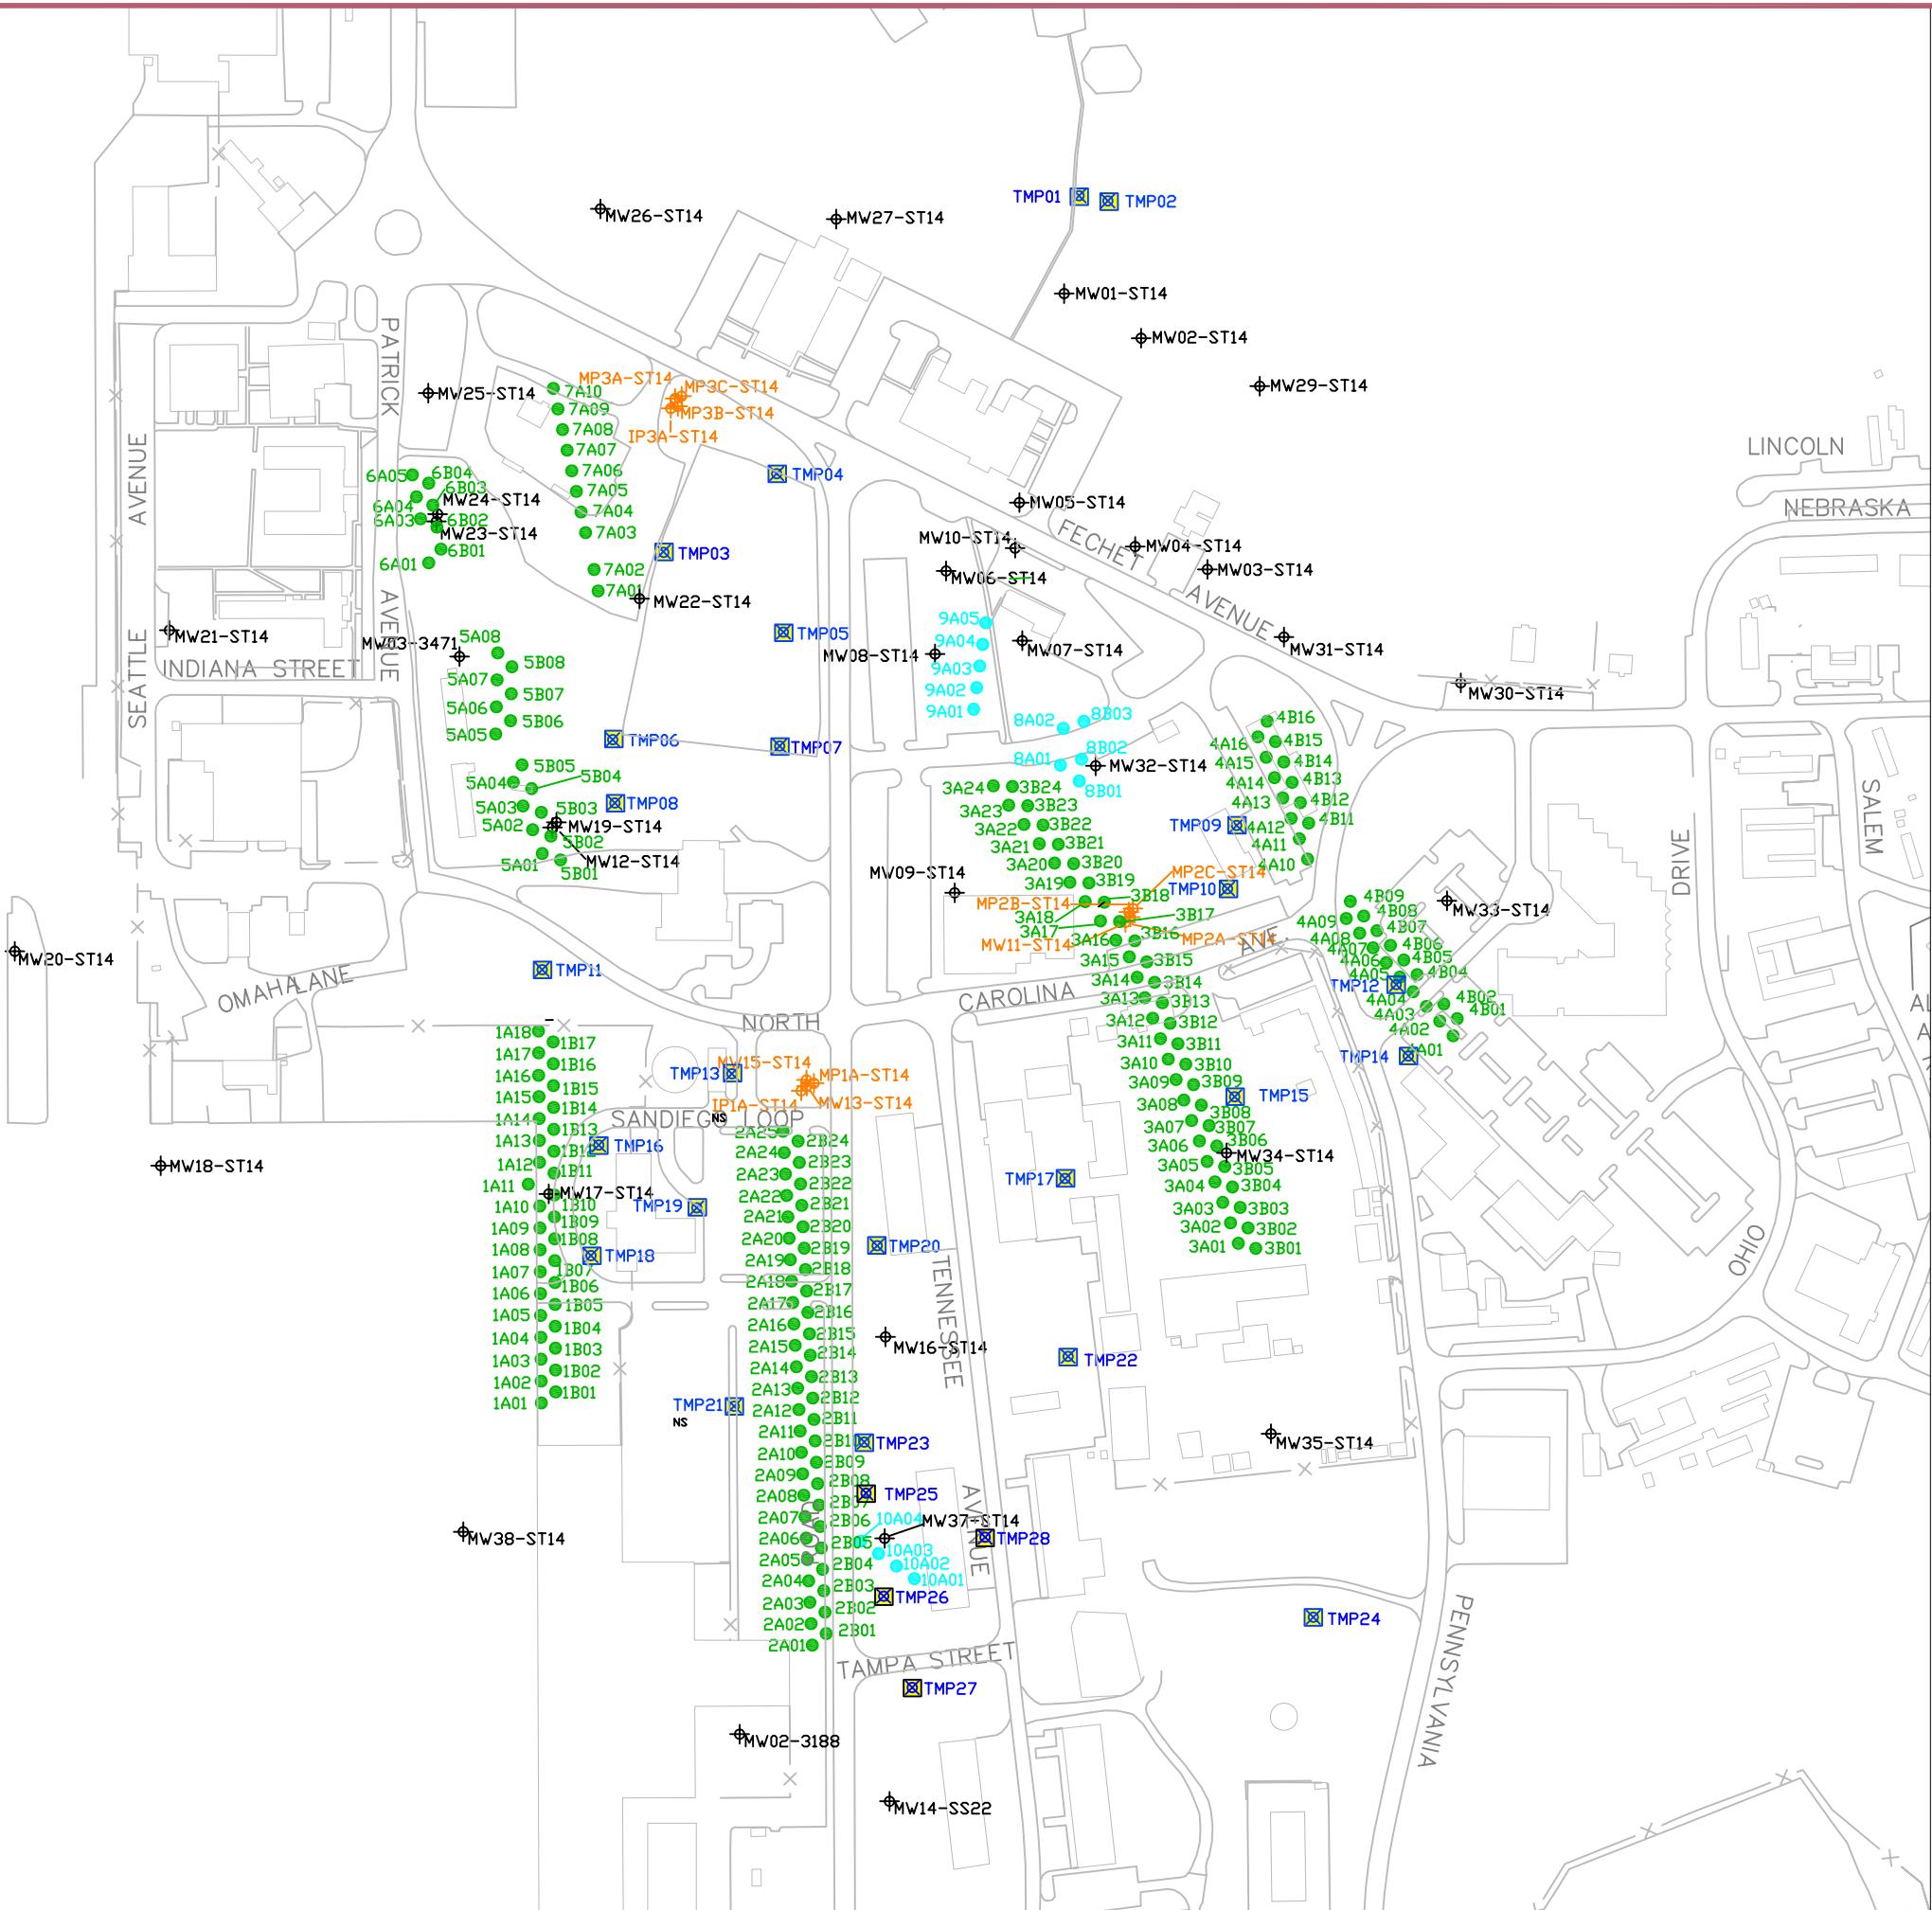

3.2 Full Scale Sodium Lactate Injections

Based on the results of the PDS and observed groundwater flow, AECOM planned substrate injections to create semi-passive bioreactive barriers (i.e., biobarriers) with anaerobic condition at fixed intervals. Within the biobarriers, anaerobic conditions promoted reductive dechlorination of TCE and CT, while intermediate metabolites further biodegraded in the aerobic intervals. Figure 3-1 illustrates the placement of the injection barriers and Figure 3-2 presents groundwater potentiometric contours based on the groundwater levels collected during the April 2010 LTM event. AECOM originally constructed seven barriers within the site, each with a number of injection wells ranging from eight injection wells on Barrier 6 to 49 injection wells in Barrier 2. In July 2009, AECOM installed three additional smaller barriers in three hotspots (Barriers 8 through 10). Table 3-1 summarizes the sodium lactate injection events that have occurred to date.

Following the first and second sodium lactate injection events, the numbers and locations of wells injected, AECOM determined the injection volumes, and strength of sodium lactate solution based on analytical lab results including concentrations of TCE and TOC, and geochemical field parameters including DO and oxidation-reduction potential (ORP). During the second injection event, conducted between December 2007 and January 2008, construction activities at Andrews AFB prohibited AECOM from injecting sodium lactate into the injection points in Barrier 7.

During the third injection event conducted in February and March 2008, and each subsequent event thereafter, AECOM excluded Barrier 4 from the injection network due to the observed decrease in TCE concentrations in the downgradient monitoring well. AECOM also excluded Barrier 6 from the injection network in July 2008 due to sufficient concentrations of residual TOC. AECOM altered the volume and frequency of injections at Barrier 5 over several injection events to evaluate the effect of substrate volume on residence time of carbon in the aquifer. During the sixth injection event conducted in November 2008, AECOM excluded Barriers 2 and 7 from the injection network due to uncertainty regarding the direction of groundwater flow in the area near Barrier 2 and relatively low TCE concentrations in wells downgradient of Barrier 7.

In July 2009, AECOM installed additional injection points in three hot spots, including the areas upgradient of MW32 (five injection points: 8A01 through 8A02; 8B01 through 8B03), upgradient of MW07 (five injection points: 9A01 through 9A05), and upgradient of MW37 (four injection points: 10A01 through 10A04). AECOM conducted the initial injection event at these Barriers in July 2009 with 250 gallons of 6% sodium lactate solution in each point. AECOM conducted subsequent injections in September and November 2009 at these locations. The September 2009 event also included six injection points within Barrier 3.

3.3 Emulsified Vegetable Oil Substrate Injections

AECOM performed a single injection event at ST-14 using EOS® (an emulsified vegetable oil organic carbon substrate) between May 17 and June 4, 2010 utilizing the existing sodium lactate injection barriers. AECOM selected EOS® as the injection substrate because it is a relatively slow-release organic carbon substrate, resulting in a longer residence time in the aquifer than sodium lactate. The EOS® injection event was the last injection event to be performed by AECOM at ST-14, and encompassed a majority of the IPs at ST-14. AECOM injected approximately 250 gallons of substrate solution into each injection point. In areas where concentrations in nearby monitoring wells (based on the October 2009 LTM event, the most recent available data when the event was planned) indicated that TCE was still elevated and/or statistically declining trends had not yet been established, a higher concentration (6 percent) of substrate was injected. In areas where groundwater concentrations of TCE had already been reduced to levels at or below MCLs because of previous substrate injections at ST-14, a lower concentration (4 percent) of substrate was injected. Table 3-2 summarizes the EOS® injection event at ST-14. AECOM submitted a technical memorandum, which provides complete details of the injection event, to Andrews AFB and USACE dated June 10, 2010 as documentation of this supplemental remedial action.

3.4 PermeOx® Plus Injections

PermeOx® Plus is a timed-release calcium peroxide powder that mixes with water to form a slurry. This substrate provides a source of oxygen to the system intended to enhance aerobic biodegradation of BTEX compounds. Based on the manufacturer's (FMC Corporation) laboratory studies, PermeOx® Plus has an estimated time-release period of 1 year. This approximation is based on laboratory data; field results will vary slightly based on site-specific conditions.

AECOM performed 40 PermeOx® Plus injections October 10–18, 2007 using direct push technology (DPT). Figure 3-3 illustrates the injection grid layout. The drilling team, supervised by AECOM personnel, advanced the DPT injections to a depth of 32 feet bgs and then raised them in 1-foot increments until the injection head reached a depth of 19 feet bgs. The slurry consisted of 120 pounds of PermeOx® Plus and 120 gallons of water for each injection point; in total, approximately 4,800 pounds of PermeOx® Plus were injected into the subsurface. Through enhanced aerobic bioremediation of BTEX in this area, AECOM intended to promote aerobic co-metabolism of TCE.

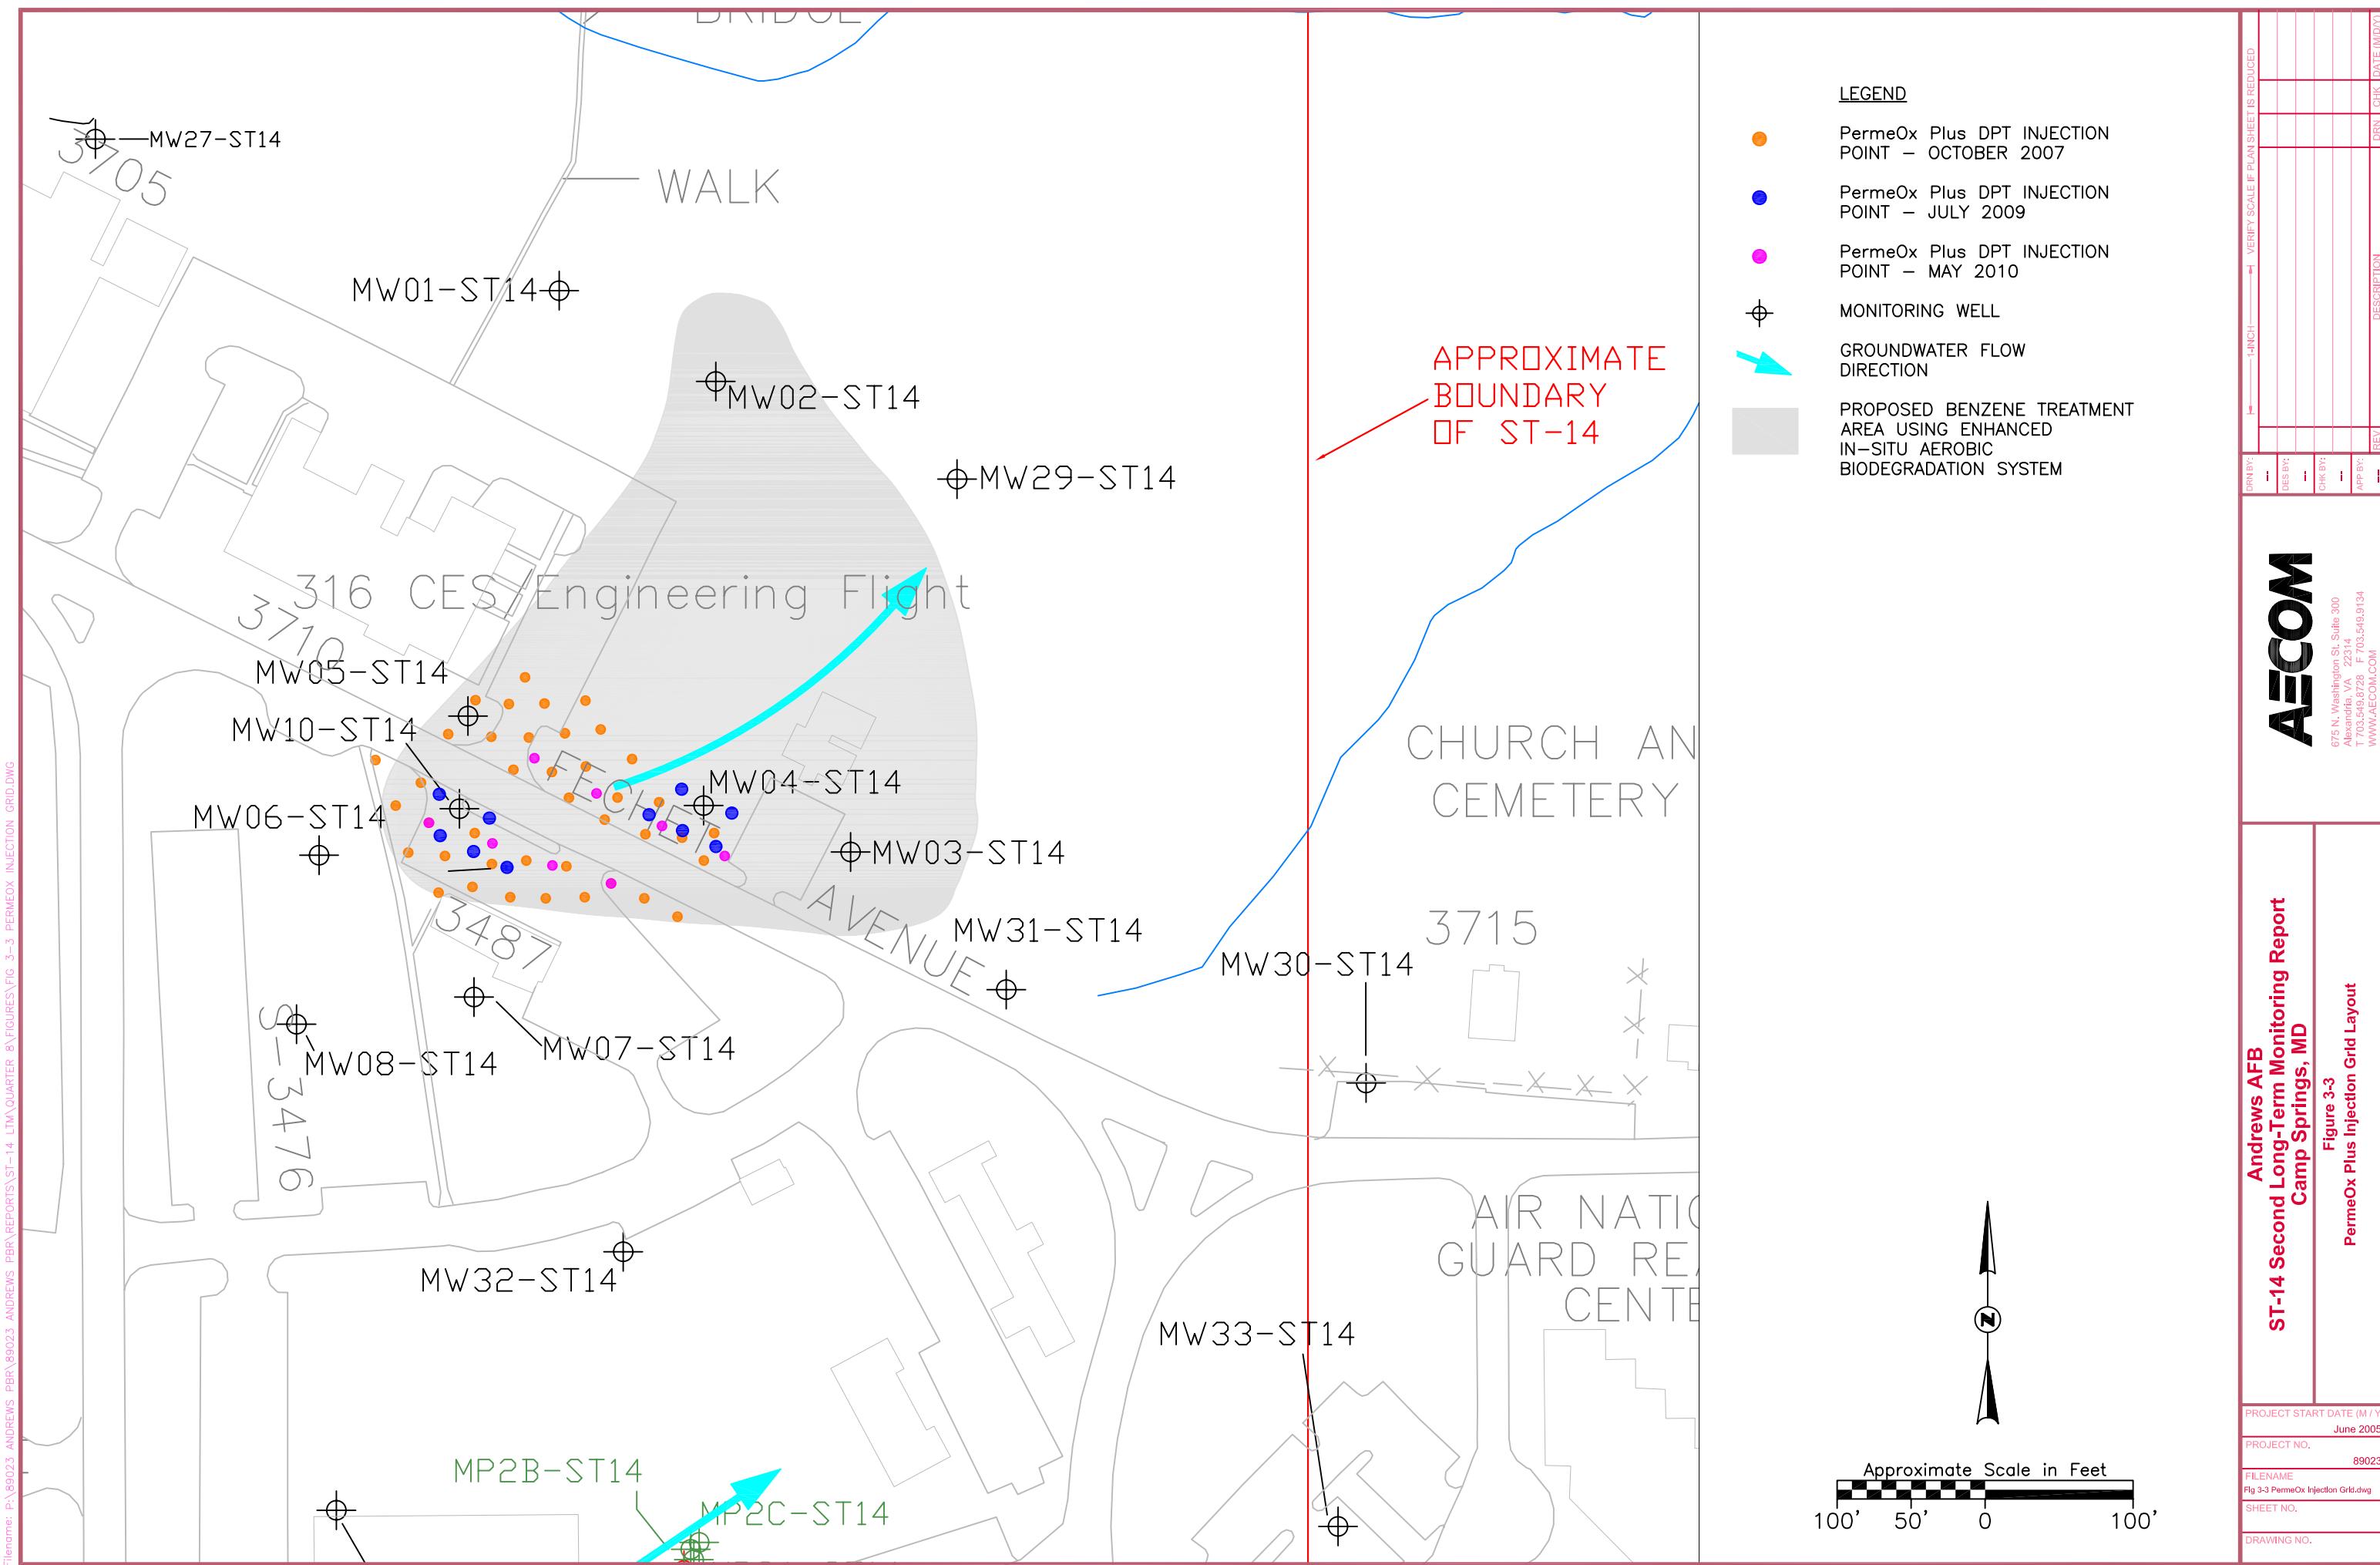

In July 2009, AECOM completed ten additional DPT PermeOx® Plus injections in the vicinity of MW10 and MW04, an area in which concentrations of BTEX had been declining, but field measurements of DO and ORP indicated that aquifer conditions had returned to an anaerobic state. In May 2010, AECOM completed eight additional DPT PermeOx® Plus injections between MW04 and MW10. AECOM documented this supplemental remedial action in a technical memorandum dated June 10, 2010. Figure 3-3 illustrates the locations of these injections.

¹ IPs 3A05 through 3A09 and 3B05 through 3B09 received a 4% EOS® solution. Most remaining IPs in Barrier 3 received a 4% EOS® solution. Refer to the Technical Memorandum (AECOM, 2010) dated June 10, 2010 for complete details.

4.0 Project Activities

The following sections summarize activities conducted during the April 2010 sampling event. Section 4.1 provides a detailed timeline of project activities. Section 4.2 outlines the groundwater sampling procedures. Section 4.3 summarizes the rationale for selecting the analyses performed on groundwater samples collected during the investigation. Section 4.4 provides a review of the analysis of field and laboratory data.

4.1 Project Timeline

The following timeline describes the remedial and monitoring activities at Site ST-14 to date:

February 2006	Installation of IPs and monitoring points for PDS
March 2006	Baseline Groundwater Sampling Event
May 2006	PDS Sodium Lactate Injection Event #1 at Test Areas 1, 2, and 3
June 2006	Groundwater Sampling Event #1
July 2006	PDS Sodium Lactate Injection Event #2 at Test Areas 1 and 2
August 2006	Groundwater Sampling Event #2
September 2006	PDS Sodium Lactate Injection Event #3 at Test Areas 1, 2, and 3
October 2006	Groundwater Sampling Event #3
June 2007	Submission of <i>Final PDS Report</i> (Earth Tech, 2007a)
September 2007	Submission of <i>Final Record of Decision</i> (Earth Tech, 2007c)
Sept. – Oct. 2007	Installation of additional injection wells and TMPs
October 2007	PermeOx® Plus Injections
October 2007	Sodium Lactate Injection Event #1
Oct. – Nov. 2007	Groundwater Sampling Event
December 2007	Sodium Lactate Injection Event #2
January 2008	Groundwater Sampling Event
Feb. – Mar. 2008	Sodium Lactate Injection Event #3
Mar. – April 2008	First Quarterly Performance Monitoring Event
April – May 2008	Sodium Lactate Injection Event #4
June – July 2008	Second Quarterly Performance Monitoring Event
July 2008	Sodium Lactate Injection Event #5
September 2008	Submission of <i>Draft Interim Remedial Action Completion Report</i> (Earth Tech, 2008)
October 2008	Third Quarterly Performance Monitoring Event
November 2008	Sodium Lactate Injection Event #6

January 2009	Fourth Quarterly Performance Monitoring Event
February 2009	Installation of additional TMPs
April 2009	Fifth Quarterly Performance Monitoring Event
May 2009	Survey of TMP elevations and site-wide gauging event
June 2009	Sodium Lactate Injection Event #7
July 2009	Supplemental PermeOx® Plus Injections
July 2009	Installation of additional sodium lactate injection wells
July 2009	Sodium Lactate Injection Event #8
July 2009	Sixth Quarterly Performance Monitoring Event
September 2009	Sodium Lactate Injection Event #9
October 2009	First Semiannual LTM Event
November 2009	Sodium Lactate Injection Event #10
January 2010	Collection of groundwater samples at MW32 and MW37
April 2010	Second Semiannual LTM Event
May – June 2010	EOS® Injection Event

4.2 Field Activities

Field activities conducted during the second semiannual LTM event in April 2010 included:

- Measurement of groundwater levels and field parameters in 38 sampling points, and
- Collection of groundwater samples for analysis from 37 sampling points and 3 surface water sampling locations.

The 38 sampling points included 30 monitoring wells, 4 TMPs, and 4 IPs.

AECOM followed protocols for groundwater sampling methods presented in the *Site-Specific Safety and Health Plan (ST-14 and SS-22)* (Earth Tech, 2006a) and the *Field Sampling Plan for the Remedial Design/Remedial Action, ST-14 and SS-22* (Earth Tech, 2006b).

Groundwater sampling procedures included the following:

- Measurement of groundwater levels with a water level meter;
- Purging of monitoring wells using low flow (minimum drawdown) sampling;
- Measurement of field-recorded parameters (including temperature, pH, specific conductance, ORP, DO, turbidity, and ferrous iron [Fe^{2+}]) during monitoring well purging; and

- Collection of groundwater samples from the purged monitoring wells using the low-flow sampling method presented in the *Field Sampling Plan for the Remedial Design/Remedial Action, ST-14 and SS-22* (Earth Tech, 2006b).

AECOM completed groundwater purging and sampling with QED SamplePro® bladder pumps with MicroPurge® control boxes and compressors. Field personnel recorded field parameters using an In-Situ® Troll 9500 or Horiba U-22 water quality meter. Refer to the *Site-Specific Safety and Health Plan (ST-14 and SS-22)* (Earth Tech, 2006a) and the *Field Sampling Plan for the Remedial Design/Remedial Action, ST-14 and SS-22* (Earth Tech, 2006b) for detailed descriptions of all sampling activities and protocols.

Field personnel decontaminated measuring and purging equipment according to the specifications in Section 5.0 of the *Field Sampling Plan for the Remedial Design/Remedial Action, ST-14 and SS-22* (Earth Tech, 2006b) and Section 5.0 of the *Installation-wide Sampling and Analysis Plan* (IT, 2002).

4.3 Sample Analysis

Based on the *Final Remedial Design Report* (Earth Tech, 2007d) for Site ST-14, the principal COCs at the site include TCE, CT, and BTEX. Potential sources of contamination include two fire department wash sites, a former aircraft wash rack, and a former vehicle wash rack where historical documents indicate the use of TCE as a degreaser. AECOM considered the chosen remedial action (i.e., injection of sodium lactate solution into the subsurface to enhance reductive dechlorination of CVOCs and injection of PermeOx® Plus into the subsurface to enhance aerobic degradation of BTEX) as most appropriate for further removal and treatment of the COCs at this site. AECOM specified LTM as part of the remedial action at Site ST-14 to confirm that contaminant concentrations are declining over time because of the remedial activities. Trend analysis of the sampling data will help determine if conditions at ST-14 require supplemental remedial activities.

AECOM subcontracted laboratory analysis of collected samples to Microbac Laboratories in Marietta, Ohio. Table 4-1 lists the analysis methods and number of samples (including quality assurance/quality control [QA/QC] samples) collected for each analysis. Figure 1-2 illustrates the monitoring wells, TMPs, and IPs sampled during the April 2010 LTM event. Appendix A includes the analytical laboratory data from the volatile organic compound (VOC) analysis. Appendix B includes the analytical laboratory data from the TOC, gasses, nitrates, alkalinity, sulfate, and metals analyses. Appendix C includes the analytical laboratory data from the PLFA analysis.

AECOM collected QA/QC samples as described in the *QA/QC Plan* (Earth Tech, 2006c). VALIDATA, located in Duluth, Georgia, conducted third party validation of the laboratory data.

4.4 Quality Assurance/Quality Control

Table 4-2 lists the analytical methods, method detection limits (MDLs), and reporting limits (RLs) for VOCs reported above detection limits.

The analytical laboratory applied data flags to the analytical data. During the data review process, VALIDATA and AECOM reviewed the analytical data and associated data flags, and assigned data qualifiers per the guidelines given in the Air Force Center for Engineering and the Environment (AFCEE) *Quality Assurance Project Plan, Version 4.0.02* (AFCEE, 2006). VALIDATA assigned the following data qualifiers to the data through the data validation process:

- **J** The analyte was positively identified, but the quantitation is an estimated value.
- **U** The analyte was analyzed, but not detected. The associated numerical value is at or below the MDL.
- **R** The data are unsuable. The analyte may or may not be present.

Table 4-1 lists the numbers of QA/QC samples, including equipment blanks, ambient blanks, matrix spike (MS) and matrix spike duplicates (MSD), trip blanks, and field duplicates.

Table 4-1
Sample Analysis Summary

Analysis	Method	Matrix	# Samples	# Equipment Blanks	# Ambient Blanks	# MS/MSDs	# Trip Blanks	# Field Duplicates	Total # Samples

5.0 Monitoring Results

This section presents the laboratory analytical results and a preliminary analysis of identified COCs. AECOM generated the COC plume maps (Figures 5-1, 5-2, 5-3, and 5-4) using Surfer®, a software package that generates concentration contours based on site data input by the user. The accuracy of the plume maps created by Surfer® increases with the quantity and density of concentration data points. The program's algorithm generates approximate plumes for Site ST-14 based on the contaminant concentrations measured at the monitoring wells and TMPs during the sampling event. Additionally, AECOM reviews and revises the contours manually to account for discrepancies in the concentration data and the automatically generated contour lines.

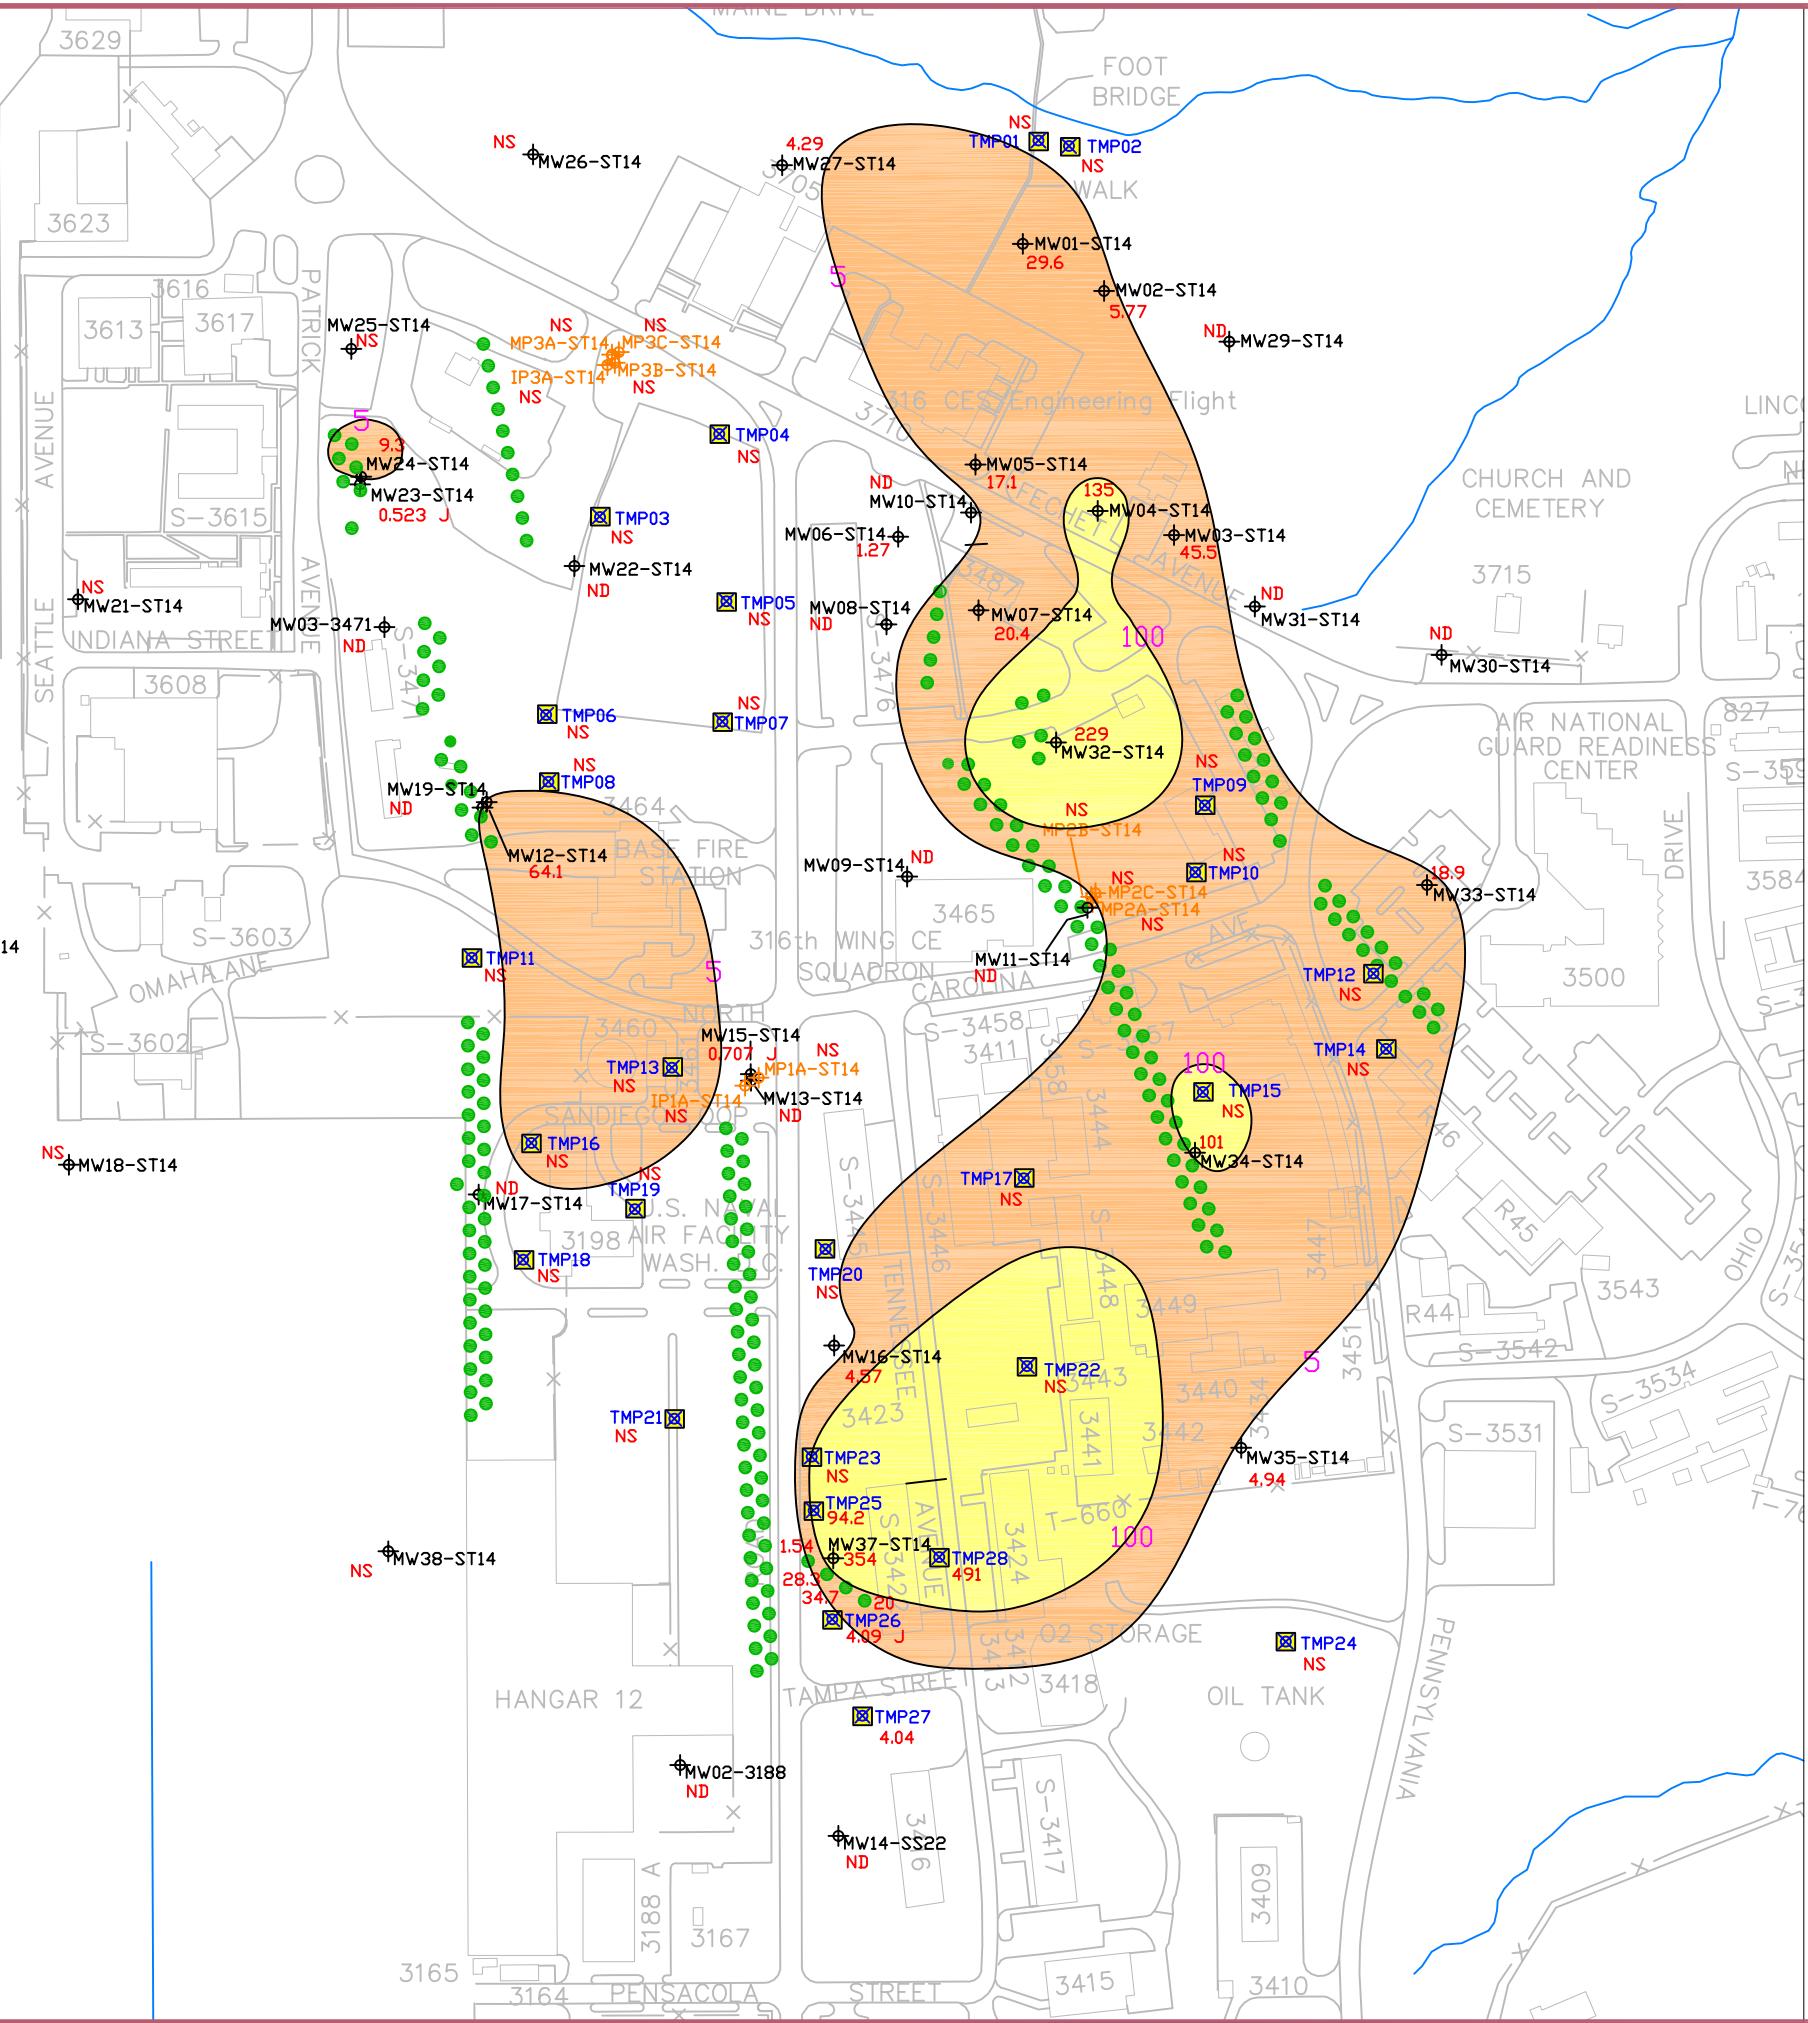

5.1 Data Summary

Figure 1-2 illustrates the locations of the monitoring wells and TMPs sampled during the April 2010 sampling event. Appendix A presents a summary of the VOC concentrations found in the groundwater samples during the April 2010 sampling event. Appendix B presents a summary of the monitored natural attenuation parameter concentrations. Appendix C presents a summary of the PLFA results obtained during each sampling event at Site ST-14. Appendix D presents a summary of key field parameters and chemical concentrations during each sampling event conducted at Site ST-14, inclusive of monitoring wells, PDS wells, TMPs, and IPs.

5.2 Summary of Field Parameters

Table 5-1 presents a summary of the field parameters measured during the April 2010 sampling event. The field parameters represent the standard low-flow stabilized values measured just prior to sample collection and include temperature, specific conductivity, DO, pH, ORP, turbidity, and ferrous iron. Appendix D presents field parameter data from each sampling event conducted at Site ST-14, as well as concentrations of select geochemical indicators and COCs.

ERD Treatment Area: Anaerobic conditions (i.e., DO is below 1.0 milligrams per liter [mg/L]) are present in some of the monitoring wells and TMPs within the active ERD treatment areas, indicating favorable conditions for ERD. These wells include MW11, MW15, MW17, MW23, MW24, MW32, MW34, TMP25, TMP26, TMP27, and TMP28. Monitoring locations that were not anaerobic during the April 2010 sampling event but are located in areas where AECOM has injected sodium lactate include MW12, MW13, MW19, and MW37. Prior to the April 2010 LTM event, AECOM last completed sodium lactate injections in the Barriers 8, 9, 10, and a portion of Barrier 3 in November 2009. Several of the other barriers had not received sodium lactate injections since July 2009 or November 2008 because of elevated TOC concentrations and decreased TCE concentrations. Because of decreasing or non-detect TCE concentrations in these areas, aerobic conditions do not present a cause for concern. Aerobic conditions (i.e., DO is above 1.0 mg/L) are generally present in areas that have not received sodium lactate injections.

mS/cm = Millisiemens per Centimeter

mV = Millivolt

NA = Not analyzed at this location

NTU = Nephelometric Turbidity Unit

¹ Well located in BTEX Treatment Area

² Water quality meter malfunctioned; parameters could not be measured.

Reducing conditions (ORP less than -50 mV) are present in many monitoring wells within the active ERD treatment areas, including MW11, MW13, MW17, MW19, MW23, MW32, TMP25, TMP56, and the Barrier 10 IPs. Monitoring locations that did not have reducing conditions during the April 2010 sampling event but are located in areas where AECOM has injected sodium lactate include MW12, MW15, MW24, MW34, MW37, and TMP27.

Following the April 2010 LTM event, AECOM completed an injection event using EOS®, an emulsified vegetable oil carbon substrate. This injection event provided a carbon source that should persist in the aquifer and promote anaerobic, reducing conditions following the end of AECOM's period of performance at ST-14. In several areas where TCE concentrations are elevated and/or DO concentrations and ORP do not indicate anaerobic, reducing conditions, AECOM injected a higher concentration of EOS®. Section 3.3 provides details of this injection event.

Neutral pH (pH 5–9) conditions are most favorable for ERD. The (March 2006) baseline pH measurements in most of the monitoring wells were just below the favorable range of pH, as is consistent with background conditions at Site ST-14 (between 4 and 5 pH). Typically, low pH can limit biological activity; however, increased pH (between 6 and 7) near the injection barriers suggests that the metabolism of sodium lactate has created a buffer capacity that is not native to the aquifer and that biodegradation can still occur without buffering the system. The April 2010 pH field measurements indicate that elevated pH levels (greater than 6) have been established in many of the wells located within or immediately downgradient of an injection barrier. Extremely basic conditions have consistently been observed in MW35 (April 2010, pH = 14+); however, this high pH is likely due to grout contamination in the monitoring well and is not representative of aquifer conditions in this area of the site.

BTEX Treatment Area: Aerobic conditions were observed in several of the wells in the northeast region of the site, including MW02, MW03, MW04, MW06, MW07, MW08, MW10, and MW31) near the site of the BTEX contamination and PermeOx® Plus injections. The supplemental PermeOx® Plus injection event, completed in May 2010, should continue to maintain elevated DO in this area and promote biodegradation of BTEX.

ORP is relatively high in the BTEX treatment area, except for MW04 and MW10 (MW04, ORP = -122 mV; MW10, ORP = -82 mV), where BTEX concentrations are highest. This shift to more reducing conditions in MW04 and MW10 is likely due to the elevated BTEX concentrations and the associated consumption of available oxygen. AECOM performed supplemental PermeOx® Plus injections in this area in May 2010, following the April 2010 LTM event, to address declining DO concentrations and increasing ORP.

5.3 Geochemical Indicators

Table 5-2 presents key geochemical indicators, including TOC, nitrate, sulfate, and methane analyzed during the April 2010 sampling event. Appendix D presents concentrations of the geochemical indicators discussed in this section from each sampling event conducted at Site ST-14, as well as select field parameters and concentrations of COCs.

mg/L = milligrams per liter

SW = Surface Water

TOC = Total Organic Carbon

µg/L = micrograms per liter

NA = Not analyzed at this location

¹ Well located in BTEX Treatment Area

Most monitoring wells at Site ST-14, especially those within or near injection barriers, have shown increased concentrations of TOC following sodium lactate injections. These changes indicate that the addition of sodium lactate effectively increased carbon loading in these areas. The increased carbon in the aquifer provides an additional carbon source for the proliferation of bacteria required for ERD. The residence time of carbon in the aquifer varies spatially throughout the site, depending on the geology and associated permeability of the subsurface. Thus, fluctuations in TOC concentrations may be expected between injection events. The supplemental EOS ® injection event in May and June 2010 will provide a slow-release carbon source, which should maintain elevated TOC concentrations over a longer period.

In the absence of oxygen in the groundwater treatment zone, anaerobic (denitrifying) bacteria will use nitrate as the primary electron acceptor. Decreased nitrate concentrations in many monitoring wells near the injection barriers suggest that nitrate is being depleted in the aquifer by microbial species using it as an electron acceptor.

Microbes can also use sulfate as a terminal electron acceptor for anaerobic biodegradation. Under anaerobic conditions, microbes typically reduce sulfate to sulfide, thus lower sulfate concentrations would be expected under anaerobic conditions. While some monitoring wells show depleted sulfate, concentrations in other monitoring wells have fluctuated and even increased since baseline sampling. During sampling, however, sulfide could be oxidized back to sulfate, explaining the higher sulfate concentrations.

Under anaerobic conditions, microbes use carbon dioxide as an electron acceptor and reduce it to methane, thus the detection of methane indicates the successful establishment of an anaerobic treatment zone. Increased methane concentrations have been observed in most of the ERD treatment areas (i.e., near injection barriers). These increases have been observed to a larger degree in the PDS Test Areas, which have received sodium lactate over a longer period.

5.4 Chemicals of Concern Groundwater Analysis Results

The primary COCs at Site ST-14 are TCE, CT, and BTEX. AECOM also monitors concentrations of DCE and VC, the by-products of TCE dechlorination. The areas with the highest concentrations of TCE include MW37 and TMP 28, located east of the parking lot of the Naval Air Facility, and MW32, located southeast of the Former East Side Gas Station. The highest concentration of TCE detected during the April 2010 sampling event was at TMP28 with a concentration of 491 µg/L. The highest concentrations of BTEX were detected in MW10 (north of the Former East Side Gas Station) with concentrations of benzene at 4,690 µg/L, toluene at 35,100 µg/L, ethylbenzene at 1,780 µg/L, and xylenes (total) at 13,160 µg/L. The highest concentration of CT was detected at MW24, near the Northern Fire Department Wash Site, at a concentration of 14.5 µg/L (Refer to Table 5-3).

Table 5-3
Principle Chemicals of Concern and Locations of Maximum Detections

Analyte	Number of Samples Above MDL	Range (µg/L)		Location of Maximum Detection	MCL (µg/L)
		Minimum Detected	Maximum Detected		
Trichloroethene	26 of 38	0.523 J	491	TMP28	5
Benzene	13 of 41	0.237 J	4,690	MW10	5
Toluene	5 of 41	0.8 J	35,100	MW10	1,000
Ethylbenzene	6 of 41	0.739 J	1,780	MW10	700

Vinyl Chloride	12 of 41	0.512 J	7.9	10A02	2

MDL = Method Detection Limit

µg/L = Micrograms per Liter

MCL = Federal Drinking Water Maximum Contaminant Levels

¹ Well located in BTEX Treatment Area

AECOM collected four surface water samples (SW04, SW05, and SW06) during the April 2010 sampling event and analyzed for VOCs and TOC. These samples contained no detectable levels of COCs.

Table 5-3 lists the primary COCs and dechlorination by-products, the number of samples that contained concentrations above the MDL, the minimum and maximum detected concentrations, the monitoring well in which the maximum concentration was detected, and the federal MCL for each contaminant. Figures 5-1, 5-2, 5-3, and 5-4 illustrate the TCE, BTEX, benzene and CT plumes, respectively, at Site ST-14 based on the April 2010 sampling event.

For comparison to baseline plume conditions, Appendix F contains maps illustrating the contaminant isoconcentrations for TCE, BTEX, and CT based on the March 2006 baseline sampling event, and the six performance monitoring events in April, July, and October 2008, and January, April, July 2009, and the two LTM events in October 2009 and April 2010. The leading edges of the TCE, BTEX, and CT plume are defined by the 5 µg/L isoconcentration line. Comparison of the April 2010 TCE plume (Refer to Figure 5-1) to the March 2006 baseline TCE plume shows a decrease in the total area of the plume, as well as decreases in some of the areas with high concentrations in previous events. Notable decreases since the baseline sampling event included:

- MW17, located near Barrier 1, upgradient of the Former Aircraft Wash Rack (TCE non-detect at MW17);
- MW12, located near Barrier 5, near the Former Southern Fire Department Wash Site (64.1 µg/L of TCE at MW12);
- MW19, also located near Barrier 5 (TCE non-detect at MW19);
- MW11, located near Barrier 3, east of the 316th Civil Engineering Squadron (TCE non-detect at MW11);
- MW32, located northeast of Barrier 3 (229 µg/L of TCE at MW32); and,
- MW37, located at the southern end of the plume (354 µg/L of TCE at MW37).

These TCE reductions have followed a period of subsurface geochemical conditions trending toward favorable for ERD. MW34, located in the southern portion of Barrier 3, exhibited a notable increase in TCE concentration since the previous LTM event in October 2009 (101 µg/L of TCE at MW34). The increased concentration at MW34 indicates rebound since October 2009, when MW34 was non-detect for TCE. Injection of EOS® in this area during the supplemental injection event in May and June 2010 will help maintain anaerobic, reducing conditions in this area.

Comparison of the April 2010 BTEX plume (Refer to Figure 5-2) to the March 2006 baseline BTEX plume shows a slight decrease in the central area of the plume, near MW10 and MW04, where concentrations of BTEX (total) have historically been the highest. The April 2010 BTEX concentrations at these locations, however, are higher than in October 2009. In April 2010, the

total BTEX concentration was 6,840 µg/L at MW04 and 54,730 µg/L at MW10. BTEX concentrations have fluctuated significantly at MW10 over several sampling events, with the minimum concentration of 1,481.8 µg/L measured in January 2009. Due to fluctuating BTEX concentrations and the small number of wells in this area, the overall size of the plume has not decreased substantially since the March 2006 baseline sampling event. The southeastern portion of the plume is represented by dashed contour lines in Figures 5-2 (BTEX) and 5-3 (benzene) due to the lack of monitoring data in this area. Based on the hydraulic gradient in this area (to the northeast), it is not expected that BTEX contamination would spread in this direction. Because benzene is the primary contaminant of toxicological concern in the BTEX area, the benzene plume is illustrated in Figure 5-3.

Comparison of the April 2010 CT plume (Refer to Figure 5-4) to the March 2006 baseline and April 2008 CT plumes indicate reduction of the plume to two locations with elevated CT concentrations above the MCL of 5 µg/L. CT was detected at MW01 at a concentration of 11.6 µg/L and at MW24 at a concentration of 14.5 µg/L. These concentrations both represent increases since October 2009.

Section 5.5 discusses trend analysis and changes in concentrations of the above noted contaminants. Appendix A presents the VOC detections for all wells sampled in April 2010. Appendix B presents the data collected from the remaining laboratory analyses performed (Refer to Table 4-1). Appendix D presents concentrations of the COCs discussed in this section from each sampling event conducted at Site ST-14, as well as select field parameters and concentrations of select geochemical parameters.

5.5 Chemicals of Concern Trend Analysis

Trend analysis of the COCs at Site ST-14 is intended to demonstrate effectiveness of the remedy and achievement of the performance objectives in the *Contract Performance Work Statement for Sites ST14 and SS22 at Andrews AFB* (June 2005). These performance objectives are to: 1) prevent further migration of the plume, 2) eliminate/treat identified source areas, and 3) sufficiently treat and demonstrate degradation of contaminants in groundwater (including achievement of MCLs within 20 to 30 years). AECOM evaluated the data collected to date and during subsequent performance monitoring events with the goal of demonstrating achievement of these performance objectives within the stated period. The potential source areas at Site ST-14 were investigated in the *CEI* (IT, 2000) and the *Final Source Area Investigation Report* (Earth Tech, 2007b). No continuing sources of groundwater contamination were identified through either report. AECOM designed the implemented remedy to target the hot spots within the larger plume and reduce TCE concentrations in those areas through ERD. Through this targeted ERD approach, the contaminants in groundwater would be sufficiently remediated (i.e., returned to beneficial reuse) within the stated period. AECOM will demonstrate achievement of groundwater MCLs within 30 years through statistical trend analysis and extrapolation of the exponential trend. AECOM completed the initial analysis using six quarters of monitoring data (following the April 2009 sampling event), and updated the analysis to include data collected during the July and October 2009 and April 2010 sampling events.

SW = Surface Water

J = Analyte reported between the mean MDL and the laboratory RL.

U = Analyte was not detected above the MDL.

¹ Well located in BTEX Treatment Area

Table 5-4 presents concentrations of the principle COCs (TCE, CT, and BTEX) and the dechlorination byproducts DCE and VC detected in the groundwater at Site ST-14 during the April 2010 sampling event. Appendix D presents concentrations of the COCs discussed in this section from each sampling event conducted at Site ST-14, as well as select field parameters and concentrations of select geochemical parameters.

AECOM completed a statistical analysis of the COC concentration data for Site ST-14 using Air Force Center for Engineering and the Environment's (AFCEE's) Monitoring and Remediation Optimization System (MAROS) software, which conducts both Mann-Kendall and linear regression analyses. Full utilization of the MAROS software requires at least four measured concentrations over a minimum of six sampling events. The April 2010 sampling event constitutes the ninth complete sampling event at Site ST-14. Additionally, the data set includes two partial monitoring events conducted in November 2007 and January 2008. The November 2007 monitoring event included 24 TMPs and 5 monitoring wells. The January 2008 monitoring event included 22 monitoring wells.

Using the data collected since the baseline sampling event in March 2006, AECOM completed the Mann-Kendall and linear regression analyses. AECOM extrapolated the exponential trends to predict achievement of MCLs within a reasonable time frame, as defined in the *Contract Performance Work Statement for Sites ST14 and SS22 at Andrews AFB* (June 2005).

5.5.1 Mann-Kendall Analysis

The Mann-Kendall analysis is a non-parametric statistical procedure that is well suited for analyzing trends in data over time (Gilbert, 1987). It does not require any assumptions about the distribution of the data (e.g., normal, lognormal, etc.) and can be used with data sets that include irregular sampling intervals and missing data (AFCEE, 2007). The 36 permanent monitoring wells at ST-14 were included in the Mann-Kendall analysis, discussed for each COC below.

TCE: Of the 36 monitoring wells included in Mann-Kendall analysis of TCE concentrations, 24 have concentrations of TCE below the MCL of 5 µg/L. Of the remaining 12 wells with concentrations of TCE above the MCL, four were classified as “Decreasing” (D), one was classified as “Probably Decreasing” (PD), and seven were classified as “No Trend” (NT). Table 5-5 includes the April 2010 TCE concentration, the Mann-Kendall statistic, and the corresponding concentration trend for each monitoring well with a TCE concentration above the MCL. A large negative Mann-Kendall statistic corresponds to stronger decreasing trends, while a large positive Mann-Kendall statistic corresponds to stronger increasing trends. The program assigns the appropriate classification (i.e., D, PD, or NT) based on the corresponding confidence in trend. The I (Increasing; no monitoring wells had this classification in April 2010) and D classifications correspond to high confidences in the trend (greater than 95%), while the intermediate classifications correspond to proportionately lower confidences in the trend. Appendix G presents the Mann-Kendall summary from the MAROS analysis of TCE, BTEX, and CT.

Table 5-5
Trichloroethene Mann-Kendall Analysis Summary

Well	April 2010 TCE Concentration ($\mu\text{g/L}$)	M-K Statistic	M-K Trend
MW12	64.1	-34	D
MW24	9.3	-37	D
MW33	18.9	-23	D
MW34	101	-24	D
MW03	45.5	-19	PD
MW01	29.6	4	NT
MW07	20.5	-3	NT
MW02	5.77	6	NT
MW04	135	9	NT
MW05	17.1	11	NT
MW32	229	14	NT
MW37	354	15	NT

$\mu\text{g/L}$ = Micrograms per Liter

D = Decreasing

PD = Probably Decreasing

NT = No Trend

For the wells classified as Decreasing or No Trend, AECOM used linear regression of the concentration data to determine the exponential curve fit and estimate the length of time until the MCL will be achieved at those locations (when mathematically possible). Section 5.5.2 discusses this analysis. Since the October 2009 LTM event, TCE concentrations at MW32 and MW37 have decreased, causing a shift in the concentration trends at these locations, which had previously been classified as increasing (I). While statistically decreasing trends have not yet been established at these locations (both classified as NT in April 2010), the observed response to supplemental substrate injections suggests that continued reductions in TCE concentrations may be expected.

BTEX: Of the 36 monitoring wells included in Mann-Kendall analysis of BTEX concentrations, 30 have concentrations of benzene below the MCL of 5 µg/L. Of the remaining six wells with concentrations of benzene above the MCL, two were classified as “Decreasing” (D), two were classified as “Stable” (S), and two were classified as “No Trend” (NT). Table 5-6 includes the April 2010 benzene concentration, the Mann-Kendall statistic, and the corresponding concentration trend for each monitoring well with a benzene concentration above the MCL. Of the 36 monitoring wells included in Mann-Kendall analysis of BTEX concentrations, 34 have concentrations of ethylbenzene below the MCL of 700 µg/L. The remaining wells (MW04 and MW10) were classified as “Stable” (S) and “No Trend” (NT), respectively. Table 5-7 includes the April 2010 ethylbenzene concentration, the Mann-Kendall statistic, and the corresponding concentration trend for the two monitoring wells with ethylbenzene concentrations above the MCL. Of the 36 monitoring wells included in Mann-Kendall analysis of BTEX concentrations, 34 have concentrations of toluene below the MCL of 1,000 µg/L. The remaining wells (MW04 and MW10) were classified as “Decreasing” (D) and “No Trend” (NT), respectively. Table 5-8 includes the April 2010 toluene concentration, the Mann-Kendall statistic, and the corresponding concentration trend for the two monitoring wells with toluene concentrations above the MCL. Of the 36 monitoring wells included in Mann-Kendall analysis of BTEX concentrations, 35 have concentrations of total xylenes below the MCL of 10,000 µg/L. The remaining well (MW10) was classified as “Stable” (S). Table 5-9 includes the April 2010 total xylenes concentration, the Mann-Kendall statistic, and the corresponding concentration trend for MW10. Appendix G presents the Mann-Kendall summary from the MAROS analysis of TCE, BTEX, and CT.

For the wells classified as Decreasing or Stable, AECOM used linear regression of the concentration data to determine the exponential curve fit and estimate the length of time until MCLs will be achieved at those locations (when mathematically possible). Section 5.5.2 discusses this analysis. Because the fluctuating BTEX concentrations at MW04 and MW10, the exponential curve fit, in many cases, is not a very good representation of the data, as discussed in Section 5.5.2.

CT: Of the 36 monitoring wells included in Mann-Kendall analysis of CT concentrations, 34 have concentrations of CT below the MCL of 5 µg/L. The remaining wells (MW01 and MW24) were classified as “No Trend” (NT) and “Stable” (S), respectively. Table 5-10 includes the April 2010 CT concentration, the Mann-Kendall statistic, and the corresponding concentration trend for the two monitoring wells with CT concentrations above the MCL. Appendix G presents the Mann-Kendall summary from the MAROS analysis of TCE, BTEX, and CT.

Table 5-6
Benzene Mann-Kendall Analysis Summary

Well	April 2010 Benzene Concentration ($\mu\text{g/L}$)	Mann-Kendall Statistic	Mann-Kendall Trend

MW10	13,160	-4	S

µg/L = Micrograms per Liter

S = Stable

Table 5-10
Carbon Tetrachloride Mann-Kendall Analysis Summary

Well	April 2010 CT Concentration (µg/L)	Mann-Kendall Statistic	Mann-Kendall Trend
MW24	14.5	-6	S
MW01	11.6	11	NT

µg/L = Micrograms per Liter

S = Stable

NT = No Trend

For the well classified as Stable (MW24), linear regression of the concentration data was used to determine the exponential curve fit and estimate the length of time until the MCL will be achieved at that locations. This calculation could not be completed for MW01 because there is not a statistically decreasing trend in the concentration data. Section 5.5.2 discusses this analysis.

5.5.2 Linear Regression Extrapolation

For the monitoring wells classified as Decreasing or Stable, and select wells classified as No Trend (where a decreasing linear regression could be obtained) through the Mann-Kendall analysis, linear regression was performed on the concentration data. Using the exponential curve generated through linear regression, the number of years until the MCL for each contaminant would be achieved at that monitoring well was predicted. The primary performance objective of the task order is to achieve MCLs within 30 years. Linear regression analysis of the concentration trends at monitoring wells classified as Increasing, Probably Increasing, or No Trend generally do not show a negative logarithmic slope, and thus do not indicate achievement of MCLs. As such, this discussion does not include these monitoring wells, noted in each subsection below. Section 3.0 discusses the additional remedial actions that AECOM has performed to date to address the increasing trends.

Table 5-11 presents a summary of the linear regression analysis for TCE, benzene, ethylbenzene, toluene, total xylenes, and CT. The coefficient of determination (R^2) (third column of Table 5-11, provides a measure of how well future outcomes are likely to be predicted by the regression analysis. Appendix H presents the trend graphs for each well discussed in this section.

TCE: Table 5-11 lists the four wells classified as D (MW12, MW24, MW33, and MW34), one well classified as PD (MW03), and two of the wells classified as NT (MW01 and MW07) for TCE concentrations. The number of years (measured from the baseline sampling event in March 2006) predicted until the MCL of 5 $\mu\text{g/L}$ is achieved at these locations ranged from 5.24 years at MW34 to 60.96 years at MW07. These estimates are based on the linear regression curves included in Appendix H. The level of confidence in the predictions listed in Table 5-11 directly correlate to the R^2 value for each well; therefore, low R^2 value is associated with a less reliable prediction. The linear regression did not generate a negative exponential slope for the TCE concentration data from MW02, MW04, MW05, MW32, and MW37; therefore, the trendlines were not decreasing and these wells were not included in Table 5-11.

BTEX: Table 5-11 lists the two wells classified as Decreasing and the two wells classified as Stable for benzene concentrations. The number of years (measured from the baseline sampling event in March 2006) predicted until the MCL of 5 $\mu\text{g/L}$ is achieved at these locations ranged from 8.08 years at MW03 to 19.81 years at MW04. These estimates are based on the linear regression curves included in Appendix H. The linear regression did not generate a negative exponential slope for the benzene concentration data from MW02 and MW03-3471; therefore, the trendlines were not decreasing and these wells were not included in Table 5-11.

Table 5-11
Linear Regression Extrapolation Summary

Well	Mann-Kendall Trend	Coefficient of Determination (R^2)	Years to MCL ¹
TRICHLOROETHYLENE (MCL = 5 µg/L)			
MW12	D	0.7049	8.74
MW24	D	0.8407	6.86
MW33	D	0.6048	13.09
MW34	D	0.1853	5.24
MW03	PD	0.2631	41.4
MW01	NT	0.4256	11.78
MW07	NT	0.0025	60.96
BENZENE (MCL = 5 µg/L)			
MW03	D	0.9087	8.08
MW04	D	0.6425	19.81
MW05	S	0.2958	10.31
MW10	S	0.0871	18.3
ETHYLBENZENE (MCL = 700 µg/L)			
MW10	NT	0.0622	0.38 ²
TOLUENE (MCL = 1,000 µg/L)			
MW04	D	0.4617	6.71
MW10	S	0.0730	8.35
CARBON TETRACHLORIDE (MCL = 5 µg/L)			
MW24	S	0.0086	7.53

MCL = Maximum Contaminant Level

µg/L = Micrograms per Liter

D = Decreasing Trend

PD = Probably Decreasing

S = Stable Trend

NT = No Trend

¹ Measured in years from baseline sampling event (March 2006)

Table 5-11 lists MW10 and the associated linear regression extrapolation for ethylbenzene concentrations. MW10, classified as NT, is predicted to achieve the MCL of 700 µg/L in 0.38 years (measured from the baseline sampling event in March 2006). This prediction, however, is not a reasonable indicator of the trend ($R^2 = 0.0622$), because the exponential fit places the trend line (Appendix H) below the current concentration. The linear regression curve for the ethylbenzene trend at MW04 is also included in Appendix H; however, no calculations could be completed because the trend line is below the MCL of 700 µg/L.

Table 5-11 lists MW04 and MW10 and the associated linear regression extrapolations for toluene concentrations. MW04, classified as D, is predicted to achieve the MCL of 1,000 µg/L in 6.71 years (measured from the baseline sampling event in March 2006). MW10, classified as S, is predicted to achieve the MCL in 8.35 years. These estimates are based on the linear regression curves included in Appendix H.

As with the ethylbenzene concentration trend at MW04, no calculations could be completed for the total xylenes concentration trend at MW10 because the trend line is below the MCL of 10,000 µg/L. The linear regression curve is included in Appendix H.

CT: Table 5-11 lists MW24 and the associated linear regression extrapolations for CT concentrations. MW24, classified as S, is predicted to achieve the MCL of 5 µg/L in 7.53 years (measured from the baseline sampling event in March 2006). This estimate is based on the linear regression curve included in Appendix H; however, it is not a reliable prediction because of the low R^2 value (0.0086). The linear regression did not generate a negative exponential slope for the CT concentration data from MW01; therefore, the trendline was not decreasing and this well was not included in Table 5-11.

5.6 Phospholipid Fatty Acid Analysis

PLFAs are essential components of living cells and therefore can be used as a proxy for the living and active microbial biomass. PLFA profiles contain detailed information on lipid structure that can be used to investigate microbial community structure and metabolic conditions. This analysis provides a broad base description of the entire microbial community with information obtained about viable biomass concentrations and community composition. PLFA analysis is a method of measuring and characterizing microbial populations. At Site ST-14, AECOM collected and analyzed samples for PLFA during the following sampling events:

- PDS – March 2006 (IP3A)
- PDS – August 2006 (IP1A, MP2A, IP3A, MP3B, MW11, and MW13);
- November 2007 (IP1A, IP3A, MW11, MW12, MW13, MW15, MW19, MW23, MW24, and MW34);
- April 2008 (MW11, MW12, MW15, MW16, MW17, MW19, MW23, MW24, MW32, MW33, MW34, and MW37);

- October 2008 (MW11, MW12, MW15, MW16, MW17, MW19, MW23, MW24, MW32, MW33, MW34, and MW37); and
- April 2009 (MW11, MW12, MW15, MW16, MW17, MW19, MW23, MW24, MW32, MW33, and MW34).

Appendix C includes the results of the PLFA analyses from the sampling events listed above. Terminally branched PLFA are common in *Firmicutes*, the bacteria responsible for reductive dechlorination. An increase in terminally branched PLFA is commonly observed as environmental conditions shift from aerobic to anaerobic conditions (i.e., the intended shift at Site ST-14). PLFA analysis reports *Firmicutes* as a proportion of the total biomass. The data collected to date suggest that the appropriate conditions were established at ST-14 to promote ERD in the full-scale treatment areas.

6.0 Conclusions

The April 2010 sampling event represents the second semiannual LTM event at Site ST-14 at Andrews AFB. The concentrations of the primary COCs (i.e., TCE, CT, and BTEX) detected in the groundwater samples were compared to results from the baseline groundwater sampling event in March 2006, the six quarterly performance monitoring events conducted from April 2008 through July 2009, and the first LTM event conducted in October 2009. The groundwater analytical data and geochemical field parameters at Site ST-14 suggest that the remedial actions performed at the site, including PermeOx® Plus and sodium lactate injections, generated favorable conditions in the treatment areas conducive to the biodegradation of the primary COCs.

AECOM completed the Mann-Kendall statistical analysis to demonstrate decreasing concentrations in the permanent monitoring wells at ST-14. This analysis identified decreasing trends in many areas of the site and stable concentrations or no trends in a few areas. The primary areas of concern include the southern portion of the site near MW37; the northeast portion of the site, near MW32; and the BTEX treatment area. COC concentrations in MW32 and MW37 have begun to decline because of the supplemental sodium lactate injections in these areas; however, statistically declining trends have not yet been established. AECOM also performed a linear regression analysis for wells with declining concentrations to predict when MCLs will be achieved based on the observed trends to date at each monitoring well. This analysis demonstrated that most of the monitoring wells with decreasing trends would achieve MCLs within 20 to 30 years (or less in some wells).

In July 2009, AECOM installed additional substrate injection points in the three identified trouble areas (near MW07, MW32, and MW37) and began a series of three sodium lactate injection events to address increasing TCE concentrations. AECOM also performed a supplemental round of PermeOx® Plus injections in July 2009 in the BTEX treatment area in order to maintain aerobic conditions. These supplemental remedial actions were largely successful in establishing the required subsurface conditions for biodegradation of COCs.

In May and June 2010, AECOM performed an injection of EOS®, a relatively slow release carbon substrate, utilizing many of the existing sodium lactate injection barriers. This injection event will provide a longer lasting source of carbon to the subsurface in order to maintain reducing conditions following the end of AECOM's period of performance at ST-14. Concentrations of COCs, TOC, DO, and ORP should be monitored to evaluate the need for future substrate injections.

The data collected during the second LTM event showed that the remedial actions implemented at ST-14 have had positive results in most of the targeted areas. Surface water sampling conducted during this event showed that dissolved contaminants in groundwater at ST-14 have not migrated to downgradient surface water drainages.

MANN-KENDALL ANALYSIS RESULTS

SUMMARY (TCE, BTEX, AND CT)

MAROS Mann-Kendall Statistics Summary

Project: Andrews AFB ST-14

User Name: McNally

Location: Andrews AFB

State: Maryland

Time Period: 2/27/2006 to 4/5/2010

Consolidation Period: No Time Consolidation

Consolidation Type: Median

Duplicate Consolidation: Average

ND Values: 1/2 Detection Limit

J Flag Values : Actual Value

Well	Source/ Tail	Number of Samples	Number of Detects	Coefficient of Variation	Mann-Kendall Statistic	Confidence in Trend	All Samples "ND" ?	Concentration Trend
TRICHLOROETHYLENE (TCE)								
MW19-ST14	S	10	9	1.04	-41	100.0%	No	D
